Understanding Stretching and Shrinking

Stretching and shrinking in grade 7 mathematics refer to transformations that change the size of a figure while preserving its shape. These transformations are often called dilations. A figure that is stretched becomes larger, while one that is shrunk becomes smaller. The essential property of these transformations is that corresponding angles remain equal, and the sides of the figure are proportional. This means the figure's shape stays the same, but the size changes according to a certain scale factor. Recognizing these transformations helps students visualize how figures relate to each other and understand similarity in geometry.

Definition of Stretching

Stretching occurs when a figure is enlarged by a scale factor greater than one. This means every side length of the figure increases proportionally. The figure retains its original shape but appears bigger. For example, if a triangle's sides are multiplied by a scale factor of 2, each side doubles in length, making the triangle twice as large in all dimensions.

Definition of Shrinking

Shrinking happens when a figure is reduced in size by a scale factor less than one but greater than

zero. This means every side length of the figure decreases proportionally. The shape remains unchanged, but the figure appears smaller. For instance, if a rectangle's sides are multiplied by 0.5, each side becomes half as long, resulting in a figure that is half the size of the original.

Scale Factors and Proportionality

Scale factors are numerical values that describe how much a figure is stretched or shrunk during dilation. Understanding scale factors is central to mastering stretching and shrinking in grade 7 math. A scale factor indicates the ratio between the dimensions of the original figure and the transformed figure. Proportionality ensures that all corresponding sides of the figures maintain a consistent ratio, preserving similarity.

Calculating Scale Factors

To calculate a scale factor, divide the length of a side in the transformed figure by the corresponding side length in the original figure. If the scale factor is greater than 1, the figure has been stretched; if it is between 0 and 1, the figure has been shrunk. For example, if an original side measures 4 units and the corresponding side in the new figure measures 6 units, the scale factor is $6 \div 4 = 1.5$, indicating a stretch.

Properties of Scale Factors

Scale factors have several important properties in geometry:

- A scale factor of 1 means the figure remains the same size (no change).
- Scale factors greater than 1 produce enlargements (stretching).
- Scale factors between 0 and 1 produce reductions (shrinking).
- Scale factors must be positive numbers.
- Corresponding angles in the original and transformed figures remain congruent.

Mathematical Calculations Involving Stretching and Shrinking

Students in grade 7 are expected to perform calculations involving stretching and shrinking to solve geometry problems. These calculations often involve finding missing side lengths, scale factors, or areas after dilation. Mastery of these skills facilitates better understanding of similarity and geometric transformations.

Finding Missing Side Lengths

When given a scale factor and some side lengths of the original figure, students can find missing side lengths of the transformed figure by multiplying the known side lengths by the scale factor.

Conversely, if the side lengths of the transformed figure are known along with the original, the scale factor can be determined by division, and missing sides calculated accordingly.

Calculating Areas After Stretching or Shrinking

The area of a figure changes by the square of the scale factor during dilation. This means if a figure is stretched by a scale factor of k , the area of the new figure is k^2 times the area of the original figure.

For example, if a square with an area of 9 square units is stretched by a scale factor of 3, the area of the new square becomes $3^2 \times 9 = 9 \times 9 = 81$ square units.

Example Problem

Consider a triangle with sides of 3 cm, 4 cm, and 5 cm. If it is stretched by a scale factor of 2.5, the new side lengths are calculated as:

1. $3 \text{ cm} \times 2.5 = 7.5 \text{ cm}$
2. $4 \text{ cm} \times 2.5 = 10 \text{ cm}$
3. $5 \text{ cm} \times 2.5 = 12.5 \text{ cm}$

The new triangle is similar to the original but larger by a factor of 2.5 in each dimension.

Real-World Applications of Stretching and Shrinking

Stretching and shrinking concepts extend beyond math class into various real-world scenarios where scaling and proportional reasoning are essential. Recognizing these applications helps grade 7 students appreciate the value of geometry in everyday life and future studies.

Architecture and Design

Architects regularly use stretching and shrinking principles when creating scale models of buildings. These models are smaller versions of the actual structures, constructed using a scale factor that shrinks the real dimensions. This allows architects and clients to visualize projects before construction begins.

Maps and Cartography

Maps are classic examples of shrinking figures, where large geographic areas are represented at a

reduced scale. Understanding how scale factors work helps users interpret distances and areas accurately on maps. The scale factor connects the map's measurements to real-world distances.

Photography and Digital Imaging

In photography and image editing, resizing images involves stretching or shrinking. Maintaining the aspect ratio ensures the image does not become distorted, which relates directly to proportional scaling and dilation concepts taught in grade 7 math.

Practice Problems and Tips for Mastery

Consistent practice with stretching and shrinking problems strengthens understanding and builds confidence. The following practice problems and strategies are effective for grade 7 students aiming to master these concepts.

Sample Practice Problems

1. A rectangle measures 6 cm by 8 cm. If it is shrunk by a scale factor of 0.5, what are the new dimensions?
2. The side of an equilateral triangle is 12 cm. If the triangle is stretched by a scale factor of 3, what is the length of each side?
3. An original figure has an area of 20 square units. If the figure is stretched with a scale factor of 4, what is the area of the new figure?
4. Given two similar triangles, the sides of one are 5 cm, 7 cm, and 9 cm, and the corresponding side of the other triangle is 15 cm. Find the scale factor and the lengths of the other sides of the larger triangle.

Tips for Success

- Always identify corresponding sides and angles before calculating scale factors.
- Remember that scale factors affect all dimensions proportionally.
- Use multiplication for stretching (scale factor > 1) and multiplication by a fraction for shrinking (scale factor < 1).
- Practice visualizing figures before and after dilation to understand transformations better.
- Check calculations of areas carefully by squaring the scale factor.

Frequently Asked Questions

What is the concept of stretching in grade 7 math?

Stretching in grade 7 math refers to enlarging a figure by multiplying its dimensions by a scale factor greater than 1, which increases its size proportionally.

How does shrinking differ from stretching?

Shrinking involves reducing the size of a figure by multiplying its dimensions by a scale factor between 0 and 1, making the figure smaller, whereas stretching increases the size.

What is a scale factor in the context of stretching and shrinking?

A scale factor is a number used to multiply the dimensions of a figure to either stretch (if greater than 1) or shrink (if between 0 and 1) it proportionally.

Can you give an example of stretching a shape by a scale factor?

If a rectangle has a length of 4 cm and width of 3 cm, stretching it by a scale factor of 2 will result in a rectangle with length 8 cm and width 6 cm.

How do coordinates change when a shape is stretched or shrunk on the coordinate plane?

When a shape is stretched or shrunk, each coordinate of its vertices is multiplied by the scale factor, changing their positions proportionally from the origin.

What happens to the area of a shape when it is stretched by a scale factor?
