Understanding Linear Programming

Linear programming is a mathematical method for determining a way to achieve the best outcome in a given mathematical model. Its applications range from maximizing profits to minimizing costs while adhering to certain constraints. The components of a linear programming problem typically include:

- **Objective Function:** This is the function that needs to be maximized or minimized.
- **Constraints:** These are the restrictions or limitations on the variables, usually expressed as linear inequalities.
- **Decision Variables:** These are the variables that decision-makers will decide the values of in order to achieve the objective.

The standard form of a linear programming problem can be expressed as follows:

$$\begin{aligned} & \text{Maximize (or Minimize)} \quad c^T x \\ & \end{aligned}$$

Subject to:

$$\begin{aligned} & Ax \leq b \\ & \end{aligned}$$
$$\begin{aligned} & \end{aligned}$$

$x \geq 0$
]

Where:

- (c) is the coefficient vector for the objective function,
- (A) is the coefficient matrix for the constraints,
- (b) is the right-hand side vector for the constraints,
- (x) is the vector of decision variables.
